Background: Physical activity declines during adolescence and strategies to combat this occurrence are both educational and public health priorities. Schools have been identified as central institutions for the promotion of physical activity among youth. While physical education is considered to be the major vehicle for physical activity promotion in the school setting, school sport provides another important opportunity to engage youth in physical activity. Little is known about students’ beliefs about the value of school sport.

Purpose: The primary aim of this study was to explore the relationship between students’ beliefs about school sport, social support received during school sport and physical self-esteem in adolescents.

Participants and setting: The sample included 249 adolescents (126 boys and 123 girls) from ten secondary schools in New South Wales, Australia. The mean age of students was 14.1 (± 1.6) years.

Research design: Cross-sectional.

Data collection and analysis: Participants completed a detailed questionnaire assessing participation in school sport, school sport beliefs, perceived social support for school sport and physical self-esteem using the Physical Self-Perception Profile (PSPP). Independent samples t-tests were used to examine gender and age differences and hierarchical regression was used to determine the relationship between students’ school sport beliefs, social support received during school sport and physical self-esteem. Separate analyses were conducted for boys and girls.

Findings: Both boys and girls considered school sport an important opportunity to be physically active. Students believed ‘enjoyment’ and selecting activities with their friends were the most important reasons for selecting school sport activities. Boys reported significantly higher levels of perceived physical strength ($F = 1.58, p < 0.05$), sport competence ($F = 0.28, p < 0.000$), physical condition ($F = 0.36, p < 0.01$), body attractiveness ($F = 1.76, p < 0.01$), and physical self-worth ($F = 3.32, p < 0.05$). The model predicting boys’ beliefs about school sport explained 17% of the variance ($F = 4.08, p < 0.01$) and the only statistically significant predictor was school sport social support ($β = 0.25, p < 0.01$). Similarly, school sport social support ($β = 0.31, p < 0.01$) was also the only significant predictor in the girls’ model which accounted for 28% of the variance in school sport beliefs ($F = 6.46, p < 0.001$).

Discussion: Students who recognised the value of school sport also reported higher levels of social support for school sport. School sport is an ideal opportunity for the promotion of physical activity and programs may be improved with increased diversity and choice for students. Furthermore, higher levels of teacher support and modelling may contribute to improved student outcomes for school sport programs.

Key words: Physical activity, school sport, attitudes, physical self-perception
Introduction

While there has been debate about whether or not physical activity levels have declined in the last 30 years (Westerterp & Speakman, 2008), evidence suggests that the current generation of children and adolescents accumulate less incidental physical activity and are less likely to engage in active transportation to school than previous generations (McDonald, 2007; Van der Ploeg, Merom, Corpuz, & Bauman, 2008). Moreover, there is compelling data to support the assertion that the largest decline in physical activity over the lifespan occurs during adolescence (Kimm et al., 2002; Nader, Bradley, Houts, McRitchie, & O’Brien, 2008). Considering the well established benefits of physical activity and the generational decrease in activity associated with adolescence, the promotion of physical activity during this time period has emerged as an important educational and public health objective.

Schools have been identified as important institutions for the promotion of physical activity among youth (Biddle & Mutrie, 2001; Centers for Disease Control & Prevention, 1997) and physical education (PE) has been recognised as the major vehicle associated with the promotion of physical activity in the school setting (Wechsler, Devereaux, Davis, & Collins, 2000). While the role of PE in the promotion of physical activity is well accepted (Daley, 2002; Fairclough, Stratton, & Baldwin, 2002; Green, 2000; Sallis, 1991), youth physical activity recommendations cannot be met through the PE curriculum alone. Additional opportunities for the promotion of physical activity in schools include: recess and lunch breaks, the physical environment of schools, active transportation, physical activity curriculum integration, extra-curricular activities and school sport.

It is also accepted that extra-curricular activities and school sport have a role to play in the promotion of activity in the school setting (Pate et al., 2006; Penney &
School Sport Beliefs

Harris, 1997; Ross, Hartford, Crawford, & Miller, 1997). Primary and secondary schools in many countries are required to provide students with weekly intra- and inter-school sport programs. These programs are generally considered to be extra-curricular as they take place beyond the school curriculum. Inter-school programs usually involve team or individual competitions between schools, while intra-school programs are competitive or non-competitive and consist of sports and a variety of recreational activities within the one school. The delivery of school sport programs differs between schools and the most common models of delivery in Australian schools are integrated, scattered and traditional. The integrated sport model involves individual classes timetabled throughout the week with specialist physical education or qualified staff delivering the sessions. Scattered sport is organised so that year groups are timetabled to have sport at the same time to enable specialist staff from both the school (i.e. physical education teachers) and community (i.e. trained instructors or coaches) to deliver sessions. Traditional school sport is organised with the whole school having sport together at the same time each week and involves non-specialist teachers along with specialist PE teachers and community members providing instruction.

While little is known about students’ beliefs about the value of school sport or about the factors associated with positive school sport beliefs, numerous studies have explored students’ beliefs about PE (e.g. Flintoff & Scraton, 2001; Rajmund, 2008; Rikard & Banville, 2006; Wang et al., 2008). Examining beliefs is important as individuals personify the perceptions they hold about phenomena, and as a result these influence behaviour (Bandura, 2004). Accordingly, the current study has been conceptualised accepting the underlying principles and theoretical framework proposed by Bandura (1977, 1986). Bandura’s (1977, 1986) theory of social learning asserts that an individual’s attitudinal disposition will impact on his or her overt response toward
the object, either directly or indirectly through mediating variables such as self-efficacy.

Unfavourable beliefs of school sport may negatively influence future participation in physical activities outside of school (Fox, 1988).

Beliefs are one of the many factors that may influence physical activity decisions. These factors are collectively referred to as ‘correlates’ or ‘determinants’ and developing an understanding of them is considered a prerequisite for designing relevant programs and policies (Sallis, Prochaska, & Taylor, 2000). A recent review concluded that physical activity was associated with a number of demographic, sociological and psychological factors including parental education, attitudes, self-efficacy, goal orientation/motivation, participation in physical education/school sports, family influences, and friend support in adolescents (Van der Horst, Paw, Twisk, & Van Mechelen, 2007). In addition, a review of the physical activity correlates among adolescent girls (Biddle, Whitehead, O'Donovan, & Nevill, 2005) found that physical self-perceptions and perceived competence were both correlates of physical activity. Physical self-perception consists of numerous sub-domains (e.g. perceived body attractiveness, perceived athletic competence, perceived strength and physical condition) (Fox & Corbin, 1989, 1990) and has been identified as a significant contributor to global self-esteem among adolescents (Santrock, 2005). While the importance of social support and physical self-perceptions to adolescent physical activity has been established, little is known about how social support and physical perceptions relate to beliefs about school sport.

The primary aim of this study was to explore the relationship between students’ beliefs about the value of school sport, perceived social support received during school sport and physical self-esteem in adolescents. Secondary aims were to identify the types of physical activities offered in school sport in Australian secondary schools, factors
School Sport Beliefs

1 influencing students’ decision making when selecting school sport options and students' beliefs of the role of school sport.

3 Methods

4 Participants

5 Ethics approval was obtained from the University of Newcastle, New South Wales (NSW), Australia and the NSW Department of Education and Training research ethics committees. Ten schools were randomly selected for the study by choosing every 4th school from the complete list of secondary schools located in the Hunter Region and Central Coast, New South Wales, Australia. An initial invitation letter was sent to the school principals of the ten schools. Three schools declined to participate in the study and they were replaced by additional schools selected randomly from the remaining schools. One year 7 class and one year 10 class from each school were randomly selected using a similar method. Year 7 and Year 10 students were included in the sample as they represent students from the first year of secondary school and the final year before school sport is no longer compulsory. Information and consent letters were distributed to 532 students from Year 7 (1st year of secondary school, age range 12-14 years) and Year 10 (4th year of secondary school, age range 15-18). The information letters provided to the students explained that the study was designed to examine their perceptions of school sport and how it contributed to their physical activity levels. A total of 249 students returned signed consent letters and participated in the study, representing a response rate of 47%.

22 Measures

23 Students completed questionnaires which were administered by trained research assistants in a classroom in exam conditions. The completion time for the questionnaire was approximately 30 minutes. Participants provided the following demographic
School Sport Beliefs

1 information: age, gender, country of birth and language spoken at home and the
2 questionnaire included the following sections:
3 Participation in school sport
4 Students were provided with an extensive list of activities commonly offered
5 for school sport and asked to indicate which of the activities they had completed as part
6 of school sport while at secondary school. Students were also provided with an
7 opportunity to list additional physical activities they had participated in during school
8 sport. Students were then asked to indicate what influenced their decisions to choose
9 certain activities by ranking their reasons from 1 (most important) to 8 (least important).
10 Reasons included- cost, convenience, enjoyment, friends, competition, staff member
11 supervising/teaching the activity, their ability in the sport or activity or the level of
12 physical activity involved in the activity. Students could also record additional reasons
13 for selecting school sport options and offer suggestions for how school sport at their
14 school could be improved.
15 Role of school sport
16 Students were asked to indicate what they perceived the role of school sport to
17 be, by ranking the roles from 1 (most important) to 5 (least important). The roles of
18 school sport included- rest from academic time, an opportunity to be physically active,
19 an opportunity to learn new skills, an opportunity to spend time with friends and an
20 opportunity to compete against other students or schools. Students were also provided
21 with an opportunity to record additional school sport roles.
22 School sport beliefs
23 The scale included five items relating to students’ beliefs about the value of
24 school sport. Students responded to a 5-point Likert scale (1 = Strongly Disagree to 5 =
25 Strongly Agree). ‘School sport...’ was the common stem and the five items were: i) is
School Sport Beliefs

1. about learning new skills, ii) has led to me increasing my physical activity levels, iii) is enjoyable, iv) has led me to start a new sport or physical activity outside of school and v) promotes an active lifestyle. Higher scores indicate more positive beliefs about the value of school sport. The internal consistency for the scale was acceptable ($\alpha = 0.74$).

Social support for school sport

This scale included five items relating to students’ beliefs about the instruction and social support students received from teachers and instructors during school sport. Students responded to a 5-point Likert scale (1 = Strongly Disagree to 5 = Strongly Agree). ‘During school sport my teacher/instructor...’ was the common stem and included the following items: i) appears enthusiastic about school sport, ii) teaches me valuable movement skills, iii) participates in physical activity or sport with me, iv) makes the activity enjoyable and v) encourages me to participate in the activity. The internal consistency for the scale was acceptable ($\alpha = 0.84$). Higher scores indicate higher levels of perceived social support.

Physical Self-Perception Profile

The Physical Self-Perception Profile (PSPP) was used in the current study to provide a measure of self-esteem in the physical domain (Fox & Corbin, 1989, 1990). The PSPP contains five, six-item subscales that measure the following components of physical self-perception: sports competence, physical condition, strength, body attractiveness and overall physical self-worth. The PSPP uses a four-choice structured alternative format to minimise socially desirable responses. Participants must first decide which of two statements best describes them and then must choose whether the statement is ‘sort of true’ or ‘really true’ for them. Each item is scored from 1 (low-self-perception) to 4 (high self-perception), providing a maximum score of 24 and minimum score of six for each subscale. The validity of the PSPP has been established (Eklund,
Whitehead, & Welk, 1997) and the internal consistency of the subscales in the study sample were as follows: sports competence ($\alpha = 0.77$), physical condition ($\alpha = 0.86$), strength ($\alpha = 0.79$), body attractiveness ($\alpha = 0.80$) and overall physical self-worth ($\alpha = 0.68$).

Piloting of questionnaire

The study questionnaire was extensively piloted with 65 students from secondary schools not involved in the current study. Following the piloting process a number of modifications were made to the questionnaire. First, additional open-ended questions were added to provide students with an opportunity to extend upon the answers they provided. Second, two questions were restructured to enable respondents to rank the importance of responses. Finally, a number of items were removed from the original school sport beliefs and social support scales because they did not provide adequate loadings to the proposed factors after the confirmatory factor analysis.

Analysis

Data were analysed using the Statistical Package for the Social Sciences (SPSS, version 16, SPSS Inc., Chicago, Ill, USA) and alpha levels were set at $p < 0.05$. All data were assessed for normality and satisfied the criteria. Structural equation modelling (SEM) in AMOS (version 16, SPSS Inc., Chicago, Ill, USA) was used to examine the psychometric properties of the school sport beliefs and social support scales developed for the current study. Confirmatory factor analysis (CFA) using maximum likelihood estimation was used to examine scale consistency and discriminant validity of the two scales. Independent samples t-tests were used to compare gender and age (i.e. Year 7 versus Year 10) differences for all relevant variables. Bivariate correlation was used to examine the relationship between psychological constructs for boys and girls separately. Hierarchical regression was used to determine the relationship between students’ school
sport beliefs, social support received during school sport and physical self-esteem. Year at school was entered in the first step, followed by social support. In the final step the five constructs from the PSPP were entered into the regression model.

**Results**

The total sample included 249 students comprising 126 boys and 123 girls from ten secondary schools. This included 134 Year 7 students and 115 Year 10 students. The mean age of participants was 14.1 (± 1.6) years and the majority were born in Australia (97.8%) and spoke English at home (98.4%). Seven schools in the study sample employed a traditional sport model whilst three schools used an integrated school sport model.

**Psychometric properties of school sport scales**

A CFA using ML estimation on the covariance matrix of the ten items of school sport beliefs and social support for school sport found that the data were an excellent fit to the hypothesized two-factor model, $\chi^2 (N = 241, df = 34) = 48.96$, Bollen-Stine bootstrap $p = 0.207$ (Figure 1). The factor loadings were significant at $p < 0.001$ and the standardised loadings ranged from 0.43 to 0.69 for the beliefs scale and 0.64 to 0.78 for the social support scale. Inspection of the structure coefficients for both scales indicated a clear distinction between the items comprising the respective factors (Table 1).

**Participation in school sport**

Boys and girls reported participating in a diverse range of activities including traditional team sports and recreational lifetime activities. The six most common activities for boys, in descending order were soccer (football), indoor soccer (indoor football), touch football (touch rugby), basketball, cricket and tennis (Table 2). The most common activities reported by girls were soccer (football), tennis, netball,
School Sport Beliefs

basketball, swimming and cricket. For boys and girls the two most important reasons for selecting a school sport option were ‘enjoyment’ and ‘friends’. ‘Level of physical activity involved’ and ‘students’ perceived level of skill and ability’ were also salient reasons for selecting school sport options. Almost one third of students (n = 81) suggested that school sport could be improved by providing a greater range of activities to choose from. For example, ‘To do more different types of sports, rather than your everyday sports’. According to students, the time available for school sport and the cost of school sport activities were also aspects of school sport that could be improved.

Role of school sport

Boys and girls both rated ‘an opportunity to be physically active’ as the number one role of school sport. According to boys, other important roles of school sport were ‘a rest from academic time’ and an ‘opportunity to learn new skills’. For girls, ‘learning new skills’ and ‘spending time with friends’ were important aspects of school sport.

Gender and age differences in psychological constructs

Boys reported significantly higher levels of perceived physical strength \( [F(1, 225) = 1.579, p < 0.05] \), sport competence \( [F(1, 232) = 0.278, p < 0.001] \), physical condition \( [F(1, 229) = 0.359, p < 0.01] \), body attractiveness \( [F(1, 226) = 1.76, p < 0.01] \), and physical self-worth \( [F(1, 224) = 3.32, p < 0.05] \). There were no significant differences between boys and girls for school sport beliefs \( [F(1, 241) = 0.674, p = 0.766] \) or perceived social support for school sport \( [F(1, 242) = 0.685, p = 0.451] \).

Year 7 students reported higher levels of physical self-worth \( [F(1, 224) = 0.879, p < .01] \), physical condition \( [F(1, 229) = 0.971, p < .01] \), body attractiveness \( (F(1, 226) = 0.272, p < .05) \), physical strength \( [F(1, 225, = 0.915, p < .05] \) and school sport social support \( [F(1, 242) = 0.107, p < .05] \). There were no significant differences
between Year 7 and Year 10 students for sport competence $[F (1, 232) = 0.296, p = 0.146]$ and school sport beliefs $[F (1, 241) = 0.151, p = 0.747]$.  

Relationship between psychological constructs

Bivariate correlations between psychological constructs are presented in Table 3 and Table 4 for boys and girls, respectively. In boys, social support for school sport was associated with physical self worth ($r = 0.20, p < 0.05$), sport competence ($r = 0.22, p < 0.05$), physical condition ($r = 0.28, p < 0.01$), body attractiveness ($r = 0.29, p < 0.01$), physical strength ($r = 0.19, p < 0.05$) and school sport beliefs ($r = 0.32, p < 0.01$). Stronger correlations were found between school sport beliefs and physical self-esteem constructs. In girls, social support was associated with sport competence ($r = 0.28, p < 0.01$), but not with any of the other physical self-esteem constructs. The relationship between school sport beliefs and social support for school sport was moderate ($r = 0.39, p < 0.001$).

The results of the regression model predicting students’ beliefs of school sport are reported in Table 5 for boys and Table 6 for girls. The model predicting boys’ beliefs about school sport explained 17% of the variance ($F = 4.08, p < 0.01$) and the only statistically significant predictor was school sport social support ($\beta = 0.25, p < 0.01$). Similarly, school sport social support ($\beta = 0.31, p < 0.01$) was also the only significant predictor in the girls’ model which accounted for 28% of the variance in school sport beliefs for girls ($F = 6.46, p < 0.001$). However, physical self-worth and sport competence were marginally significant predictors of school sport beliefs in the girls’ model ($0.05 \leq p < 0.10$).

Discussion

The primary aim of this study was to explore the relationship between adolescents’ school sport beliefs, social support received during school sport and physical self-
School Sport Beliefs

1 esteem. Higher levels of perceived social support were associated with more positive
2 beliefs about the value of school sport for both boys and girls. While there were
3 moderate correlations between school sport beliefs and perceived sport competence in
4 boys and girls, these associations were not significant in the multiple regression models.
5 The study also sought to identify the activities engaged in during school sport and
6 students’ reasons for choosing certain activities. The most common activities were
7 traditional team sports and the number of students participating in lifetime and
8 recreational activities was relatively small. Both boys and girls considered school sport
9 provided an opportunity to be physically active and ‘enjoyment’ and ‘spending time
10 with friends’ were the most important reasons for selecting school sport options.
11 An important finding from this study was that students, who perceived higher
12 levels of social support, encouragement, and motor skill development from their
13 teachers and instructors during school sport, exhibited more positive feelings about
14 school sport. Students with more positive feelings about school sport are more likely to
15 seek opportunities to be physically active. Although beliefs are generally not considered
16 to be direct predictors of physical activity, they may be important precursors to
17 important mediators of behaviour such as self-efficacy (Lubans, Foster, & Biddle,
18 2008). Recent reviews of the correlates of physical activity in adolescents concluded
19 that social support from family and friends was associated with higher levels of physical
20 activity (Biddle et al., 2005; Van der Horst et al., 2007). However, studies that have
21 examined the relationship between teacher support and modelling and physical activity
22 have found no association (Biddle & Goudas, 1996; Zakarian, Hovell, Hofstetter, Sallis,
23 & Keating, 1994). It is possible that social support received during school sport is
24 related to activity level in school sport only, but not to overall physical activity levels.
25 Additional factors may facilitate and impede physical activity behaviour outside of the
School sport is one of many opportunities for the promotion of physical activity in the secondary school setting and the provision of increased social support from teachers and instructors may contribute to increased physical activity and enjoyment in adolescence.

‘Enjoyment’ and ‘spending time with friends’ were the most important reasons for selecting school sport activities. Previous studies have found that enjoyment and social support from friends are important correlates of physical activity among adolescents (Biddle et al., 2005; Lubans & Morgan, 2009; Van der Horst et al., 2007).

Unlike physical education, school sport generally provides students with an opportunity to choose their own activities, which they can select with their friends. Finding ways to enhance students’ enjoyment, while supporting the social aspects of school sport, are important considerations for teachers.

The regression models predicting school sport beliefs explained 17% and 28% of the variance for boys and girls, respectively. Additional explanatory variables may need to be included in future models. Previous studies have linked actual motor competence to physical activity among youth (Castelli & Valley, 2007; Erwin & Castelli, 2008; Fisher et al., 2005; Okely, Booth, & Patterson, 2001; Raudsepp & Pall, 2006; Wrotniak, Epstein, Dorn, Jones K.E., & Kondilis, 2006) and motor proficiency might explain additional variance. This study has shown that school sport is dominated by competitive team sports and it is plausible to suggest that students with higher levels of motor proficiency also have more positive beliefs about the value of school sport. If school sport is focused on team sport activities it is unlikely that students with lower skill levels will enjoy the experience and develop positive beliefs about the value of school sport.
The majority of students reported engaging in competitive team sports for school sport, which is consistent with previous studies that have explored students’ activities in physical education (Hill & Cleven, 2005; Hill & Hannon, 2008). Although students generally follow a prescribed program of study in PE, the importance of providing students with choice over curricular activities in PE has been proposed in the literature (Hill & Hannon, 2008). It is interesting to note that approximately one third of the study sample suggested that their school sport program could be improved by providing more choice and variety in the types of physical activities available. It has been noted that school-based PE and school sport should progress from a focus on general movement activity and skill development in primary schools to a focus on the health, fitness and behavioural components of physical activity in the secondary school setting (Strong et al., 2005). However, research suggests that PE and school sport are dominated by competitive team sport activities (Fairclough et al., 2002; Hill & Cleven, 2005; Hill & Hannon, 2008; MacFadyen, 1999). The ten most common activities reported by boys and girls included only two lifetime activities (i.e. swimming and fitness activities). While it cannot be determined from the current study how many lifetime activities were provided by schools and not selected by students, based on the student responses to open-ended questions, it appears that students are dissatisfied with the existing choices available. Students also suggested that the time available for school sport and the cost of school sport activities were aspects of school sport that could be improved. Although school sport may not cost students in all countries (e.g. United Kingdom), in Australia, many school sport options are only available to students willing and able to pay additional fees. Those students unable to pay for transportation and/or entry to some recreational activities (e.g. roller skating, health and fitness centre), are generally
provided with traditional team sports as an alternative. As stated previously, it is important that adolescents participate in a range of lifetime activities that will encourage future participation. Schools have an important role to play in overcoming the barriers to physical activity experienced by students from disadvantaged backgrounds. Similar to previous studies (Daley, 2002; Raustorp, Ståhle, Gudasic, Kinnunen, & Mattsson, 2005) the boys in this study reported significantly higher levels of physical self-esteem than the girls. Perceived sport competence was the only physical self-esteem construct related to girls’ perceived social support. This is an interesting finding and suggests that girls with higher levels of perceived sport competence also perceive higher levels of social support during school sport. As discussed previously, school sport is dominated by competitive team sports and highly skilled girls participating in inter-school sport competitions may receive more social support than girls participating in intra-school programs. The relationship between school sport beliefs and sport competence was moderate for both boys and girls. Research suggests that perceived lack of physical skill is a major barrier to participation in physical activity among adolescents (Fairclough, 2003; Hill & Hannon, 2008; Wallhead & Buckworth, 2004). A recent longitudinal study found that FMS competency in childhood predicted physical activity in adolescence (Barnett, van Beurden, Morgan, Brooks, & Beard, 2009) and that the relationship was mediated by perceived sport competence (Barnett, Morgan, van Beurden, & Beard, 2008). It could be argued that the current school sport focus on team sports may reward students with high levels of motor proficiency. Individuals with higher levels of perceived and actual competence are more likely to recognise games, sports and physical activities as enjoyable and seek additional opportunities to be active (Fisher et al., 2005; Stodden et al., 2008).

Implications
This study has important implications for the delivery of school sport programs in the secondary school setting. First, it is important that teachers recognise the importance of social support and role modelling in school sport. In Australian schools many school sport activities are delivered by non-specialist teachers (i.e. not by physical education teachers). Many of these teachers do not have adequate training and experience to deliver high quality school sport programs and additional in-servicing and professional development may assist these individuals. Without essential knowledge and skills, non-specialist teachers may find it difficult to efficiently organise practical activities and provide the necessary instruction and feedback to motivate students. Furthermore, as the fear of public failure and embarrassment are powerful barriers to participation in physical education and school sport programs (Biddle, 2001), it is important that teachers recognise that students’ efforts and abilities will be scrutinised by others in the group. Teachers should be aware of the importance of perceived sport competence and provide social support and opportunities for skill mastery. Furthermore, teachers should embrace the social nature of school sport and encourage students to choose activities that they can participate in with their friends. It is important that schools find a balance between providing students with enjoyable active opportunities and creating a social environment that will increase students’ levels of intrinsic motivation to enhance future participation. This may help students lacking in confidence to overcome their anxieties about participation. Second, while school sport should build upon and extend beyond the PE curriculum, it is important school sport remain distinct from PE and provide students with diversity and an opportunity to engage in a variety of ‘lifetime’ physical activities, such as health-related fitness and recreational activities. A common criticism of PE is that students follow a set program and are given limited opportunity to choose their activities. While adolescents generally have positive beliefs
School Sport Beliefs

about physical activity, many students possess a negative attitude towards PE and
eventually develop negative attitudes to physical activity (Corbin, 2002). Finally, the
impact of school sport physical activity programs should be evaluated to determine the
types of activities and programs that contribute to improved activity levels and
cognitions relating to activity.

Strengths and limitations

This is the first study to explore the relationship between students’ beliefs
about the value of school sport, perceived social support and physical self-perceptions.
Moreover, the study involved a random sample of schools combined with randomly
selected classes from the study schools. However, there are a number of limitations in
the current study that should be noted. First, only schools in the Hunter Region and
Central Coast of New South Wales, Australia were included in this study, which may
limit the generalizability of the results. However, while the sample size was relatively
small, the random selection of schools and classes has provided a representative sample
of students from the region. Second, the study involved a cross-sectional design and
therefore causal relationships cannot be established. Third, the study did not assess
physical activity and therefore the relationship between social support, school sport
beliefs and physical activity cannot be determined. Finally, no school sport sessions
were observed to determine the actual level of social support provided by teachers.

Conclusions

This study has shown that students who report higher levels of social support
during school sport also report more positive beliefs about the value of school sport.
Perceived sport competence was moderately associated with school sport beliefs in
boys and girls. The majority of students reported participation in competitive team
sports and a third of students suggested that their school sport program could be
improved with greater choice and diversity in the types of activities offered. Both boys
and girls considered school sport provided an opportunity to be physically active and
‘enjoyment’ and ‘spending time with friends’ were the most important reasons for
selecting school sport options. Secondary schools should consider these issues when
designing their school sport programs.
